1. Introduction

A brief introduction to VMware Virtual SAN

Introduction

Introduction to Virtual SAN

VMware Virtual SAN is radically simple, enterprise-class storage for hyper-converged infrastructure (HCI). Uniquely embedded in the VMware vSphere hypervisor, Virtual SAN delivers flash-optimized, high-performance storage. It leverages commodity x86 server components to drastically lower TCO by up to 50% and deliver all-flash solutions for as low as half the price of competitive hybrid HCI systems. Seamless integration with vSphere and the entire VMware stack makes it the simplest storage platform for business-critical workloads, virtual desktop infrastructure (VDI), remote office IT, disaster recovery, and DevOps infrastructures. Customers of all industries and sizes trust Virtual SAN to run their most important applications.

Key Benefits

- **Radically Simple** Configure with just a few clicks using the vSphere Web Client and automate management using storage policies. Eliminate expensive, complex, purpose-built storage array hardware and automate management of storage service levels through VM-centric policies.
- **High Performance** Deliver up to [150,000 IOPs](#) per host and over 6 Million IOPs per cluster with predictable sub-millisecond response time from a single, all-flash configuration. Built on an optimized I/O data path designed for flash speeds, Virtual SAN delivers much better performance than virtual appliance and external device solutions.
- **Elastic Scalability** Easily grow storage performance and capacity by adding new nodes or drives without disruption. Linearly scale capacity and performance from 2 to 64 physical vSphere hosts per cluster.
- **Lower TCO** Lower storage costs by up to 50% by deploying standard x86 servers with local storage devices for low upfront investment and by shrinking data center footprint and operational overheads. Further improve total cost of ownership with features like deduplication, compression, erasure coding, iSCSI target services, and automation with PowerCLI.
- **Enterprise-Class Availability** Enable maximum levels of data protection and application availability with built-in tolerance for disk and host failures, stretched cluster configurations, and compatibility with DR solutions such as [VMware Site Recovery Manager](#) and vSphere Replication.
- **Advanced Management** Management for storage, compute and networking with advanced performance and capacity monitoring all within the vSphere Web Client.

Use cases for Virtual SAN include mission-critical applications, test and development, remote and branch offices, disaster recovery sites, and virtual desktop infrastructure (VDI). Virtual SAN supports a number of configuration options such as 2-node clusters for small implementations at remote offices to clusters as large as 64 nodes delivering over 6 million IOPS. Stretched clusters can also be configured to provide resiliency against site failure and workload migration with no downtime for disaster avoidance. VMware provides the market-leading HCI platform powered by vCenter Server, vSphere and Virtual SAN.

2. What's New in Virtual SAN 6.5

The new features and benefits of Virtual SAN 6.5

Witness Traffic Separation

Separating Virtual SAN Witness Traffic

New in vSphere 6.5 and Virtual SAN 6.5 is the ability to separate witness network traffic from the network that connects the two physical hosts in a two-node cluster. This configuration option reduces complexity by eliminating the need to create and maintain static routes on the physical hosts. Security is also improved as the data network (between physical hosts) is completely separated from the WAN for witness traffic.

A Virtual SAN Witness is a virtual appliance that is utilized in stretched clusters and two-node configurations. The witness acts as a "tie-breaker" in certain events such as a network partition between hosts in a 2-node cluster. The witness virtual appliance stores metadata such as witness components. It does not store data components such as VM Home and virtual disk (VMDK) files.

Two-node VSAN cluster configurations are commonly used for branch offices and remote locations running a small number of virtual machines. A witness virtual appliance must not run on either of the two physical nodes in the cluster as this would defeat the purpose of the witness. The recommended location for the witness virtual appliance(s) is a primary data center connected to the remote locations by a WAN. Having the witness virtual appliances centrally located facilitates ease of management.

Two-Node Direct-Connect

Two-Node Configuration with Crossover Cables

Physical Hosts in a two-node cluster can be connected using crossover cables. Organizations with existing 100Mbps or 1Gbps networking hardware can continue to utilize this equipment and enable 10Gbps connections for Virtual SAN and vMotion. All-flash Virtual SAN configurations (including two-node) require 10Gbps connectivity and vMotion performance is enhanced using faster connections between hosts. Connection reliability between the physical hosts is also improved with direct connections.

As with any storage fabric, redundant connections are recommended. In addition to providing resiliency against a NIC or cable failure, two connections between physical hosts enables administrators to separate Virtual SAN from vMotion traffic. It is possible for vMotion to saturate a 10Gbps link when migrating multiple virtual machine simultaneously, e.g., when a host is put into maintenance mode. This scenario has the potential to impact Virtual SAN performance while the migrations are taking place. The figure below shows one possible configuration that would prevent Virtual SAN and vMotion from using the same connection unless there is a NIC or cable failure.

For more information on network configuration options and recommendations, see the [vSphere documentation](#) and the [Virtual SAN Network Design Guide](#).

iSCSI Target Service

iSCSI Target Service

Block storage can be provided to physical workloads using the iSCSI protocol. The Virtual SAN iSCSI target service provides flexibility and potentially avoids expenditure on purpose-built, external storage arrays. In addition to capital cost savings, the simplicity of Virtual SAN lowers operational costs.

The Virtual SAN iSCSI target service is enabled with just a few mouse clicks. CHAP and Mutual CHAP authentication is supported. Virtual SAN objects that serve as iSCSI targets are managed with storage policies just like virtual machine objects.

Enable Virtual SAN iSCSI target service i

Select a default network to handle the iSCSI traffic. You can override this setting per target.

Default iSCSI network:

Default TCP port:

Default authentication:

When you enable iSCSI target service, you create a home object that stores metadata for iSCSI target service. (similar to the VM Home object in a virtual machine). The storage policy for the home object should have a Number of failures

Storage policy for the home object:

After the iSCSI target service is enabled, iSCSI targets and LUNs can be created. The screen shot below shows target and LUN configuration options.

Target IQN:	<input type="text" value="iqn.1998-01.com.vmware:367BCE07-D86F-756C-9B0A-7F5EBAB005A4"/>
Target alias:	<input type="text" value="DB"/>
Target storage policy:	<input type="text" value="Virtual SAN Default Storage Policy"/>
Network:	<input type="text" value="vmk1"/>
TCP port:	<input type="text" value="3260"/>
Authentication:	<input type="text" value="None"/>

Add your first LUN to the iSCSI target (Optional)

LUN ID:	<input type="text" value="0"/>
LUN alias:	<input type="text" value="file"/>
LUN storage policy:	<input type="text" value="Virtual SAN Default Storage Policy"/>
LUN size:	<input type="text" value="500"/> <input type="text" value="GB"/>

Virtual SAN Storage Consumption

Storage space	1,000 GB
Initially reserved storage space	0 B
Reserved flash space	0 B

The last step is adding initiator names or an initiator group, which controls access to the target, as shown here.

iqn.1998-01.com.vmware:367bce07-d86f-756c-9b0a-7f5ebab005a4 - Allow Initiator A... >>

Initiator names:

Add multiple initiators by separating them with a comma.(i.e. iqn1, iqn2, iqn3)

Initiator group

In nearly all cases, it is best to run workloads in virtual machines to take full advantage of Virtual SAN's simplicity, performance, and reliability. However, for those use cases that truly need block storage, it is now possible to utilize Virtual SAN iSCSI Target Service.

Cloud Native Application Storage

Cloud Native Application Storage

New application architecture and development methods have emerged that are designed to run in today's mobile-cloud era. For example, "DevOps" is a term that describes how these next-generation applications are developed and operated. "Container" technologies such as [Docker](#) and [Kubernetes](#) are a couple of the many solutions that have emerged as options for deploying and orchestrating these applications. VMware is embracing these new application types with a number products and solutions. Here are a few examples:

[Photon OS](#) - a minimal Linux container host optimized to run on VMware platforms.

[Lightwave](#) - an open source project comprised of enterprise-grade identity and access management services.

[Photon Controller](#) - a distributed, multi-tenant ESXi host controller optimized for containers.

Cloud native applications naturally require persistent storage just the same as traditional applications. Virtual SAN for Photon Controller enables the use of a Virtual SAN cluster in cloud native application environments managed by Photon Controller. Virtual SAN for Photon Controller includes developer-friendly APIs for storage provisioning and consumption. APIs and a graphical user interface (GUI) geared toward IT staff are also included for management and operations.

[vSphere Integrated Containers Engine](#) is a container runtime for vSphere, allowing developers familiar with Docker to develop in containers and deploy them alongside traditional virtual machine workloads on vSphere clusters. vSphere Integrated Containers Engine enables these workloads to be managed through the vSphere GUI in a way familiar to vSphere admins. Availability and performance features in vSphere and Virtual SAN can be utilized by vSphere Integrated Containers Engine just the same as traditional virtual machine environments.

[Docker Volume Driver](#) enables vSphere users to create and manage Docker container data volumes on vSphere storage technologies such as VMFS, NFS, and Virtual SAN. This driver makes it very simple to use containers with vSphere storage and provides the following key benefits:

- DevOps-friendly API for provisioning and policy configuration.
- Seamless movement of containers between vSphere hosts without moving data.
- Single platform to manage - run virtual machines and containers side-by-side on the same vSphere infrastructure.

Virtual SAN along with the solutions above provides an ideal storage platform for developing, deploying, and managing cloud native applications.

Full Featured PowerCLI Commandlets

New and Improved PowerCLI Cmdlets

VMware's PowerCLI implementation is one of the most widely adopted extensions to the framework. It features a plethora of functions that abstract the vSphere API down to simple and powerful cmdlets including a number of cmdlets for Virtual SAN. This makes it easy to automate a number of actions from simply enabling Virtual SAN to deployment and configuration of a Virtual SAN stretched cluster. Here are a few examples of what can be accomplished with Virtual SAN and PowerCLI:

[Assigning a Storage Policy to Multiple VMs with PowerCLI](#)

[Sparse Virtual Swap Files](#)

[Automated Deployments](#)

With each new release of vSphere PowerCLI and Virtual SAN APIs, the functionality becomes more robust. Cmdlets have been added and improved for these and many other operations:

- Enabling deduplication and compression
- Enabling the performance service
- Configuring the health check service
- Creating all-flash disk groups
- Fault domain management
- Stretched cluster configuration
- Selecting the data migration option for maintenance mode
- Retrieve capacity information

vSphere administrators and DevOps shops can utilize these new cmdlets to lower costs by enforcing standards, streamlining operations, and enabling automation for vSphere and Virtual SAN environments.

512e Drive Support

512e Storage Devices

Disk drives have been using a native 512-byte sector size. Due to increasing demands for larger capacities, the storage industry introduced new formats that use 4KB physical sectors. These are commonly referred to as "4K native" drives or simply "4Kn" drives. Some 4Kn devices include firmware that emulates 512 byte (logical) sectors while the underlying (physical) sectors are 4K. These devices are referred to as "512B emulation" or "512e" drives.

vSphere 6.5 and Virtual SAN 6.5 support the use of 512e drives. The latest information regarding support for these new drive types can be found in this VMware Knowledge Base Article: [Support statement for 512e and 4K Native drives for VMware vSphere and vSAN \(2091600\)](#)

3. Architecture

Choice of hardware platforms, network requirements, Virtual SAN embedded in vSphere, and 2-node direct-connect configurations.

Hardware and Deployment Options

Servers with Local Storage

Virtual SAN clusters consist of any number of physical server hosts from two to 64. Each host contains flash devices (all-flash configuration) or a combination of magnetic disks and flash devices (hybrid configuration) that contribute cache and capacity to the Virtual SAN distributed datastore. Each host has one to five disk groups. Each disk group contains one cache device and one to seven capacity devices.

For all-flash configurations, the flash device(s) in the cache tier are used for write caching only as read performance from the capacity flash devices is more than sufficient. Two grades of flash devices are commonly used in an all-flash Virtual SAN configuration: Lower capacity, higher endurance devices for the cache layer and more cost effective, higher capacity, lower endurance devices for the capacity layer. Writes are performed at the cache layer and then de-staged to the capacity layer, only as needed. This helps extend the usable life of the lower endurance flash devices in the capacity layer.

In a hybrid configuration, one flash device and one or more magnetic drives are configured as a disk group. A disk group can have up to seven magnetic drives for capacity. One or more disk groups are utilized in a vSphere host depending on the number of flash devices and magnetic drives contained in the host. Flash devices serve as read and write cache for the Virtual SAN datastore while magnetic drives make up the capacity of the datastore. By default, Virtual SAN will use 70% of the flash capacity as read cache and 30% as write cache.

Deployment Options

Virtual SAN Ready Nodes are typically the easiest, most flexible approach when considering deployment methods. Virtual SAN Ready Nodes are x86 servers, available from all of the leading server vendors that have been pre-configured, tested and certified for Virtual SAN. Each Ready Node is optimally configured for Virtual SAN with the required amount of CPU, memory, network, I/O controllers and storage devices.

Turn-key appliances such as [Dell EMC VxRail](#) provide a fully-integrated, preconfigured, and pre-tested VMware hyper-converged solution for a variety of applications and workloads. Simple deployment enables customers to be up and running in as little as 15 minutes.

Custom configurations using jointly validated components from a number of OEM vendors is also an option. The [Virtual SAN Hardware Quick Reference Guide](#) provides some sample server configurations as directional guidance and all components should be validated using the [VMware Compatibility Guide for Virtual SAN](#).

Network Considerations

All-flash Virtual SAN configurations require 10Gb network connectivity. 1Gb connections are supported for hybrid configurations although 10Gb is recommended. Currently, Virtual SAN requires the use of [multicast](#) on the network. Multicast communication is used for host discovery and to optimize network bandwidth consumption for the metadata updates. This eliminates the computing resource and network bandwidth penalties that unicast imposes in order to send identical data to multiple recipients.

Support for using crossover cables in a 2-node cluster is new in Virtual SAN 6.5. Utilizing crossover cables eliminates the need to procure and manage a 10Gb network switch for these hosts, which lowers costs especially in scenarios such as remote office deployments. This configuration also improves availability and provides complete separation of Virtual SAN witness traffic from data traffic.

For more information on Virtual SAN network requirements and configuration recommendations, see the [Virtual SAN Network Design Guide](#).

Virtual SAN Embedded in vSphere

Storage Virtual Appliance Disadvantages

Storage in a hyper-converged infrastructure (HCI) requires compute resources that have been traditionally offloaded to dedicated storage arrays. Most HCI solutions require the deployment of storage virtual appliances to some or all of the hosts in the cluster to provide storage services to each host. These virtual appliances typically require CPU and/or memory reservations to avoid resource contention, which can result in performance degradation. Running a virtual appliance on every host in the cluster reduces the overall amount of compute resources available to run regular virtual machine workloads. Consolidation ratios will likely be lower and total cost of ownership rises when these storage virtual appliances are present and competing for the same resources as regular virtual machine workloads.

Storage virtual appliances can also introduce additional latency, which negatively affects performance. This is due to the number of steps required to handle and replicate write operations as shown in the figure below.

Virtual SAN Embedded in the vSphere Hypervisor

Virtual SAN does not require the deployment of storage virtual appliances or the installation of a vSphere Installation Bundle (VIB) on every host in the cluster. Virtual SAN is embedded in the vSphere kernel and typically consumes less than 10% of the compute resources on each host. Virtual SAN does not compete with other virtual machines for resources and the IO path is shorter.

A shorter IO path and the absence of resource-intensive storage virtual appliances enables Virtual SAN to provide extreme performance with minimal overhead. Higher consolidation ratios translate into lower total costs of ownership.

4. Simple Deployment and Operations

Enabling Virtual SAN, health check, proactive tests, capacity and performance.

Enabling Virtual SAN

Enabling Virtual SAN

Virtual SAN is built into vSphere. Virtual SAN is enabled with just a few mouse clicks. There is no requirement to install additional software and/or deploy virtual storage appliances to every host in the cluster. Simply click the Enable Virtual SAN checkbox to start the process. Deduplication and compression can also be enabled at that time.

Turn ON Virtual SAN

Add disks to storage	Manual ▼ Requires manual claiming of any new disks on the included hosts to the shared storage.
Deduplication and compression	Enabled ▼ <input type="checkbox"/> Allow Reduced Redundancy i Changes require a rolling reformat of all disks in the VSAN cluster. Depending on the amount of data stored, this might take a long time. ⚠ Enabling this feature would lead to some performance degradation.

The next step is claiming local storage devices in each host for the Virtual SAN cache and capacity tiers. One or more disk groups are created in each host. Each disk group contains one cache device (flash) and one or more capacity devices (flash or magnetic). Virtual SAN pools these local storage device together to create a pool of shared storage.

Disk Groups

Disk Group	1 ▲	State	Type	Virtual SAN H
▼ 10.144.97.85		Connected		Healthy
Disk group (020000000055cd2e404c0da778494e54454c20)		Mounted	All flash	Healthy
Disk group (020000000055cd2e404c0e9e18494e54454c20)		Mounted	All flash	Healthy
▼ 10.144.97.86		Connected		Healthy
Disk group (020000000055cd2e404c0da73c494e54454c20)		Mounted	All flash	Healthy
Disk group (020000000055cd2e404c0e9e15494e54454c20)		Mounted	All flash	Healthy
▼ 10.144.97.87		Connected		Healthy

The process of enabling Virtual SAN takes only a better of minutes. This is a tribute to the simplicity of Virtual SAN - especially when you compare it to other enterprise-class hyper-converged and traditional storage systems, which typically take much longer to set up.

Health Check

Health Service

Virtual SAN 6.2 features a comprehensive health service that actively tests and monitors a number of items such as hardware compatibility, network connectivity, cluster health, and capacity consumption. The health service is enabled by default and configured to check the health of the Virtual SAN environment every 60 minutes.

Virtual SAN Health (Last checked: Today at 7:12 PM)

Test Result	Test Name
✓ Passed	▶ Hardware compatibility
✓ Passed	▶ Network
✓ Passed	▶ Physical disk
✓ Passed	▶ Data
✓ Passed	▶ Cluster
✓ Passed	▶ Limits
✓ Passed	▶ Performance service

The Health service is quite thorough in the number of tests it performs. As an example, proper network configuration is essential to a healthy Virtual SAN cluster and there are 11 tests in the Network section of the Virtual SAN Health user interface.

✓ Passed	▼ Network
✓ Passed	All hosts have a Virtual SAN vmknic configured
✓ Passed	All hosts have matching multicast settings
✓ Passed	All hosts have matching subnets
✓ Passed	Basic (unicast) connectivity check (normal ping)
✓ Passed	Hosts disconnected from VC
✓ Passed	Hosts with connectivity issues
✓ Passed	Hosts with Virtual SAN disabled
✓ Passed	MTU check (ping with large packet size)
✓ Passed	Multicast assessment based on other checks
✓ Passed	Unexpected Virtual SAN cluster members
✓ Passed	Virtual SAN cluster partition

If an issue is detected, a warning is visible in the Virtual SAN user interface. Clicking on the warning provides more details about the issue. For example, a controller driver that is not on the hardware compatibility list (HCL) will trigger a warning. In addition to providing details about the warning, Virtual SAN Health also has an Ask VMware button, which brings up the relevant VMware Knowledge Base article.

vSphere and Virtual SAN support a wide variety of hardware configurations. The list of hardware components and corresponding drivers that are supported with Virtual SAN can be found in the [VMware Compatibility Guide](#). It is very important to use only hardware, firmware, and drivers found in this guide to ensure stability and performance. The list of certified hardware, firmware, and drivers is contained in a hardware compatibility list (HCL) database. Virtual SAN makes it easy to update this information, for use by the Health Service tests. If the environment has Internet connectivity, updates can be obtained directly from VMware. Otherwise, HCL updates can be downloaded to enable offline updates.

If an issue does arise that requires the assistance of VMware Support, it is easy to upload support bundles to help expedite the troubleshooting process. Clicking the Upload Support Bundles to Service Request... button enables an administrator to enter an existing support request (SR) number and upload the necessary logs with just a few mouse clicks.

Proactive Tests

Proactive Tests

Virtual SAN proactive tests enable administrators verify Virtual SAN configuration, stability, and performance to minimize risk and confirm that the datastore is ready for production use. Three proactive tests are available:

- VM creation test
- Multicast performance test
- Storage performance test.

The VM creation test creates and deletes a small virtual machine on each host confirming basic functionality. The multicast test verifies multicast is working properly on each host and performance meets Virtual SAN requirements. The following figure shows the results of a VM creation test.

Proactive Tests

Name	Last Run Result
VM creation test 	 Passed
Multicast performance test 	N/A
Storage performance test 	N/A

VM creation test - Details

Hosts VM Creation Test Result

Host	Status
 10.144.97.85	success
 10.144.97.86	success
 10.144.97.87	success
 10.144.97.88	success

The storage performance test is used to check the stability of the Virtual SAN cluster under heavy I/O load. There are a number of workload profiles that can be selected for this test as shown below. Keep in mind the storage performance test can affect other workloads and tasks. This test is intended to run before production virtual machine workloads are provisioned on Virtual SAN.

Run Storage performance test

Run workload for at least 5 minutes to get representative results. Run for hours to test stability of the cluster

Duration: Minutes

Workload: **Low stress test**

Storage Policy:

- Basic sanity test, focus on Flash cache layer
- Stress test
 - Performance characterization - 100% Read, optimal RC usage
 - Performance characterization - 100% Write, optimal WB usage
 - Performance characterization - 100% read, optimal RC usage after warmup
 - Performance characterization - 70/30 read/write mix, realistic, optimal flash cache usage

Capacity Reporting

Capacity Reporting

Capacity overviews are available in the Virtual SAN user interface making it easy for administrators to see used and free space at a glance. Deduplication and compression information is also displayed.

Capacity Overview	Deduplication and Compression Overview										
<table border="1"> <tr> <td>Used - Total</td> <td>2.09 TB</td> </tr> <tr> <td>Deduplication and compression overhead</td> <td>788.58 GB</td> </tr> <tr> <td>Free</td> <td>11.70 TB</td> </tr> </table>	Used - Total	2.09 TB	Deduplication and compression overhead	788.58 GB	Free	11.70 TB	<table border="1"> <tr> <td>Savings</td> <td>5.35 TB</td> </tr> <tr> <td>Ratio</td> <td>3.56x</td> </tr> </table>	Savings	5.35 TB	Ratio	3.56x
Used - Total	2.09 TB										
Deduplication and compression overhead	788.58 GB										
Free	11.70 TB										
Savings	5.35 TB										
Ratio	3.56x										

Information is also available showing how much capacity various object types are consuming. Note that percentages are of used capacity, not of total capacity.

Used Capacity Breakdown

Breakdown of the used capacity before it was deduplicated and compressed.

Group by: ▾

This list provides more details on the object types in the Used Capacity Breakdown chart:

- Virtual disks: Virtual disk consumption before deduplication and compression
- VM home objects: VM home object consumption before deduplication and compression
- Swap objects: Capacity utilized by virtual machine swap files
- Performance management objects: When the Virtual SAN performance service is enabled, this is the amount of capacity used to store the performance data
- File system overhead: Capacity required by the Virtual SAN file system metadata
- Deduplication and compression overhead: deduplication and compression metadata, such as hash, translation, and allocation maps
- Checksum overhead: Capacity used to store checksum information
- Other: Virtual machine templates, unregistered virtual machines, ISO files, and so on that are consuming Virtual SAN capacity

Performance Reporting

Performance Service

A healthy Virtual SAN environment is one that is performing well. Virtual SAN includes a number of graphs and data points that provide performance information at the cluster, host, virtual machine, and virtual disk levels. Time Range can be modified to show information from the last 1-24 hours or a custom date and time range.

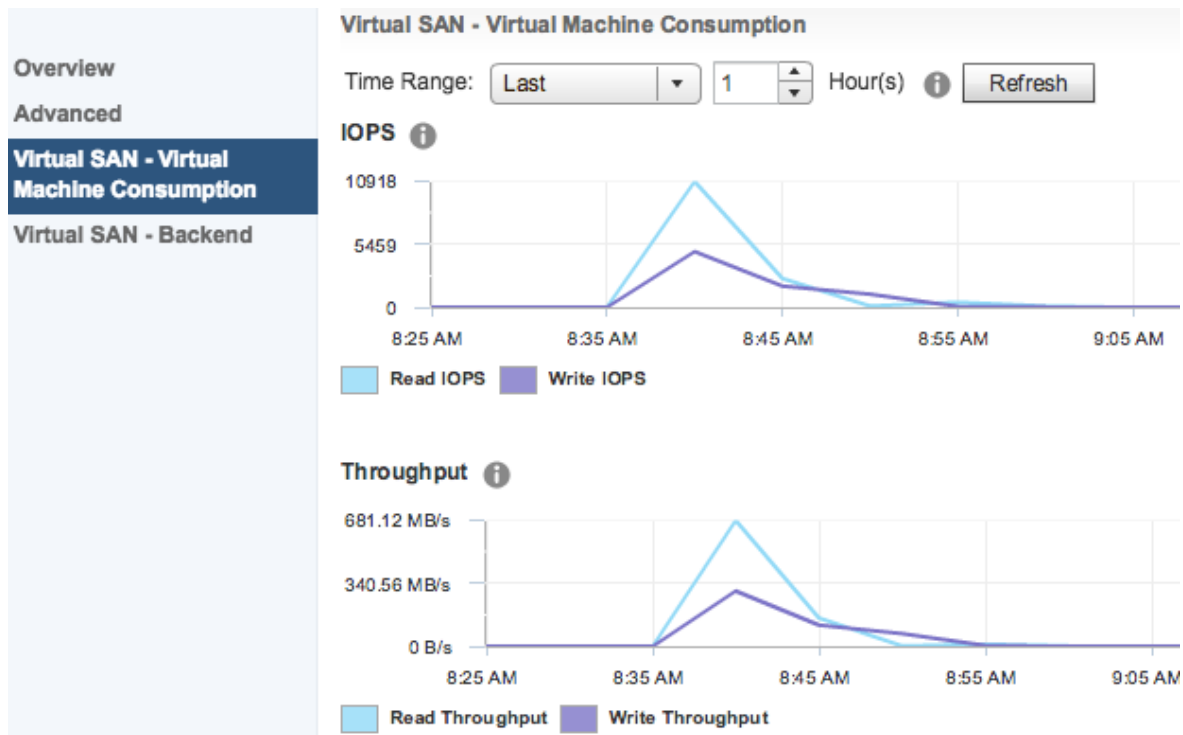

The performance service is enabled at the cluster level. The performance history database is stored as a Virtual SAN object independent of vCenter. A storage policy is assigned to the object to control space consumption, availability, and performance of that object. If the object becomes unavailable, performance history for the cluster cannot be viewed until access to the object is restored.

The performance service is turned off by default. A few mouse clicks are all that is needed to enable the service.

Performance Service is Turned ON		<input type="button" value="Turn off"/>	<input type="button" value="Edit storage policy ..."/>
Stats object health	✓ Healthy		
Stats object UUID	9e30ed57-ceed-facc-e9f5-002590c61478		
Stats object storage policy	📁 Virtual SAN Default Storage Policy		
Compliance status	✓ Compliant		

Cluster Metrics

At the cluster level, the performance monitoring service shows performance metrics for virtual machines running on Virtual SAN. These metrics provide quick visibility to the entire Virtual SAN cluster. A number of graphs are included such as read and write IOPs, read and write throughput, read and write latency, and congestion.

Backend consumption stems from activities such as metadata updates, component builds, etc. For example, a virtual machine with a number of failures to tolerate set to 1 with a failure tolerance method of RAID-1 (Mirroring). For every write IO to a virtual disk, two are produced on the backend - a write to each component replica residing on two different hosts.

Host Metrics

In addition to virtual machine consumption and backend performance metrics, disk group and individual disk performance information is available at the host level. Seeing metrics for individual disks eases the process of troubleshooting issues such as failed storage devices.

Virtual Machine Metrics

Virtual SAN performance information for individual virtual machines and virtual disks. Metrics include IOPS, throughput, and latency. The figure below shows virtual disk-level Virtual SCSI throughput and latencies for reads and writes.

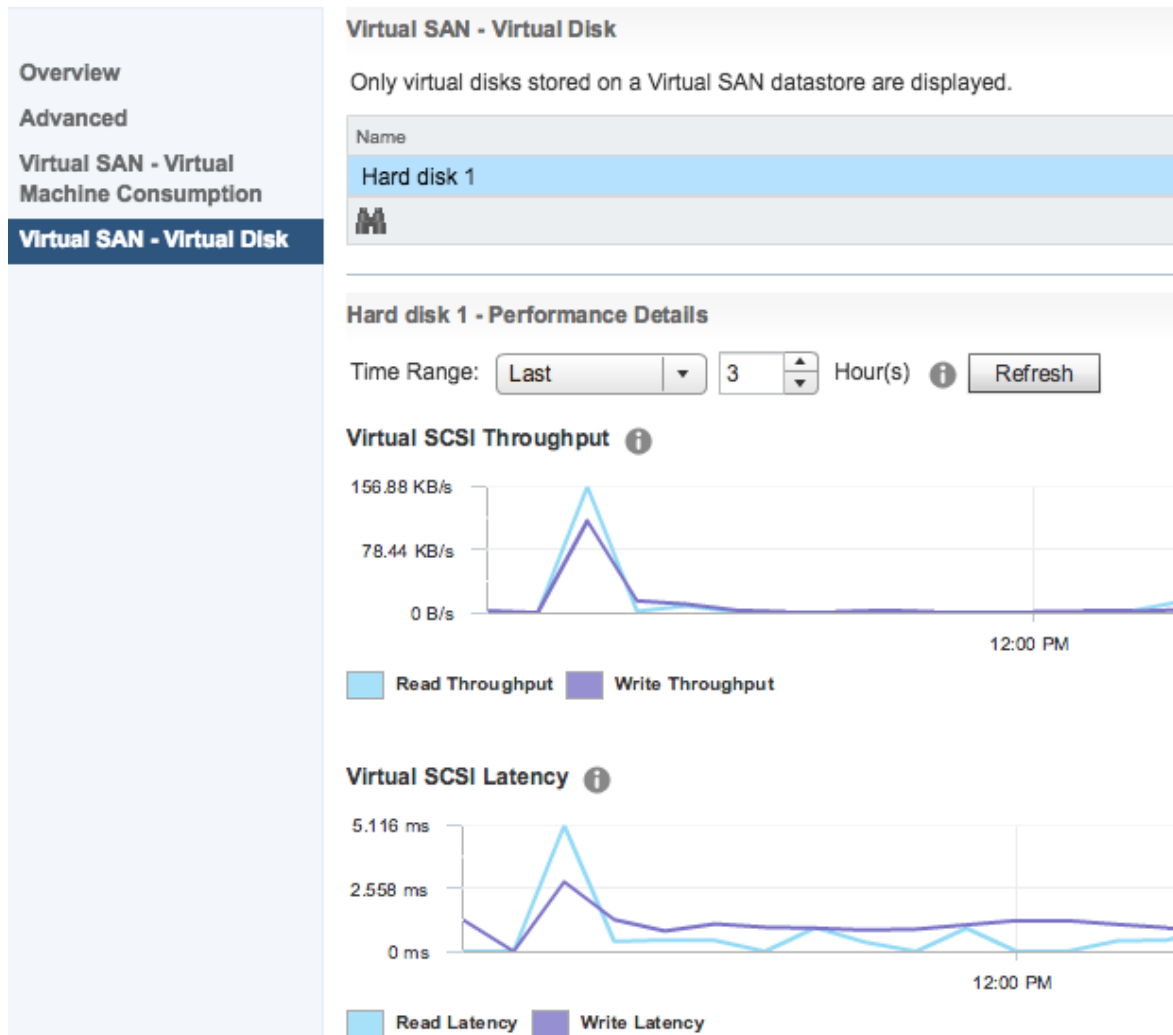

Figure x. Virtual Disk Performance

Performance Service

A healthy Virtual SAN environment is one that is performing well. Virtual SAN includes a number of graphs and data points that provide performance information at the cluster, host, virtual machine, and virtual disk levels. Time Range can be modified to show information from the last 1-24 hours or a custom date and time range.

The performance service is enabled at the cluster level. The performance history database is stored as a Virtual SAN object independent of vCenter. A storage policy is assigned to the object to control space consumption, availability, and performance of that object. If the object becomes unavailable, performance history for the cluster cannot be viewed until access to the object is restored.

The performance service is turned off by default. A few mouse clicks are all that is needed to enable the service.

Performance Service is Turned ON		<input type="button" value="Turn off"/>	<input type="button" value="Edit storage policy ..."/>

Compliance status	✔	Compliant	

Cluster Metrics

At the cluster level, the performance monitoring service shows performance metrics for virtual machines running on Virtual SAN. These metrics provide quick visibility to the entire Virtual SAN cluster. A number of graphs are included such as read and write IOPs, read and write throughput, read and write latency, and congestion.

Backend consumption stems from activities such as metadata updates, component builds, etc. For example, a virtual machine with a number of failures to tolerate set to 1 with a failure tolerance method of RAID-1 (Mirroring). For every write IO to a virtual disk, two are produced on the backend - a write to each component replica residing on two different hosts.

Host Metrics

In addition to virtual machine consumption and backend performance metrics, disk group and individual disk performance information is available at the host level. Seeing metrics for individual disks eases the process of troubleshooting issues such as failed storage devices.

Virtual Machine Metrics

Virtual SAN performance information for individual virtual machines and virtual disks. Metrics include IOPS, throughput, and latency. The figure below shows virtual disk-level Virtual SCSI throughput and latencies for reads and writes.

5. Policy Based Management and Automation

Creating and modifying a storage policy, component placement, and automation (PowerCLI, Python, APIs)

Storage Policy Based Management

Traditional Storage Management

Traditional storage models utilize LUNs or volumes. A LUN or a volume is commonly configured with a specific disk configuration such as RAID to provide a specific level of performance and availability. The challenge with this model is each LUN or volume is confined to providing only one level of service regardless of the workloads that it contains. This leads to the provisioning of numerous LUNs or volumes in an attempt to provide the right levels or storage services to each workload. Maintaining a large number of LUNs or volumes leads to management complexity. Deployment and management of workloads and storage in traditional storage environments can be time consuming and error prone.

Storage Policy Based Management

Storage Policy Based Management (SPBM) enables precise control of the storage services. Similar to other storage solutions, Virtual SAN provides services such as availability level, striping for performance, and the ability to limit IOPS. Policies that contain one or more rules are created using the vSphere Web Client.

Use rule-sets in the storage policy i

▼ Placement

Storage Type: VSAN

Failure tolerance method i RAID-5/6 (Erasure Coding) - Capacity ✕

Number of failures to tolerate i 1 ✕

Number of disk stripes per object i 1 ✕

<Add rule>

These policies are assigned to virtual machines and individual objects such as a virtual disk. Storage policies can easily be changed and/or reassigned if application requirements change. These changes are performed with no downtime and without the need to migrate (Storage vMotion) virtual machines from one LUN or volume to another. This approach makes it possible to assign and modify service levels based on specific application needs even though the virtual machines reside on the same datastore.

Automation

Automation

Virtual SAN features an extensive management API and multiple software development kits (SDKs) to provide IT organizations options for rapid provisioning and automation. Administrators and developers can orchestrate all aspects of installation, configuration, lifecycle management, monitoring, and troubleshooting of Virtual SAN environments. This is especially useful in large environments and geographically disbursed organizations to speed up deployment times, reduce operational costs, maintain standards, and orchestrate common workflows.

SDKs are available for several programming languages including .NET, Perl, and Python. They are available for download from [VMware Developer Center](#) and include libraries, documentation, and code samples. For example, this Python script can be used to generate Virtual SAN capacity information: [Virtual SAN Capacity - Total and Free from vCenter](#)

Virtual SAN APIs can also be accessed through [vSphere PowerCLI](#) cmdlets. IT administrators can automate common tasks such as assigning storage policies and checking storage policy compliance. Consider a repeatable task such as deploying or upgrading two-node Virtual SAN clusters at 100 retail store locations. Performing each one manually would take a considerable amount of time. There is also a higher risk of error leading to non-standard configurations and possibly downtime. vSphere PowerCLI can instead be used to ensure all of the Virtual SAN clusters are deployed with the same configuration. Lifecycle management, such as applying patches and upgrades, is also much easier when these tasks are automated.

This video demonstrates a number of operations from creating a new cluster to configuring Virtual SAN using just a few lines of vSphere PowerCLI code:

[vSphere PowerCLI: Creating a Cluster and Configuring Virtual SAN](#)

6. Enterprise Availability

Resiliency against disk, host, rack, and entire site failures.

Objects and Component Placement

Objects

Virtual SAN (VSAN) is an object datastore with a mostly flat hierarchy of objects and containers (folders). Items that make up a virtual machine (VM) are represented by objects. These are the most common object types you will find on a VSAN datastore:

- VM Home, which contains virtual machine configuration files and logs such as the VMX and NVRAM files
- VM Swap
- Virtual Disk (VMDK)
- Delta Disk (snapshot)
- Memory Delta, which is present when the checkbox to snapshot a VM's memory is checked

There are a few other objects that might be found on a VSAN datastore such as the VSAN performance service database and VMDKs that belong to iSCSI targets.

Components

Each object consists of one or more components. The number of components that make up an object depends primarily on a couple things: The size of the objects and the storage policy assigned to the object. The maximum size of a component is 255GB. If an object is larger than 255GB, it is split up into multiple components. The image below shows a 600GB virtual disk split up into three components.

Type	Component State	Host	Cache Disk Name
▼ RAID 0			
Component	 Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da
Component	 Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da
Component	 Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da

In most cases, a VM will have a storage policy assigned that contains availability rules such as Number of Failures to Tolerate and Failure Tolerance Method. These rules will also affect the number of components that make up an object. As an example, let's take that same 600GB virtual disk and apply the Virtual SAN Default Storage Policy, which uses the RAID-1 mirroring failure tolerance method and has the number of failures to tolerate set to one. The 600GB object with three components will be mirrored on another host. This configuration provides two full copies of the data distributed across two hosts so that the loss of a disk or an entire host can be tolerated. Below is an image showing the six components (three on each host). A seventh component, the witness, is created by VSAN to "break the tie" and achieve quorum in the event of a network partition between the hosts. The witness object is placed on a third host.

Type	Component State	Host	Cache Disk Name
▼ RAID 1			
▼ RAID 0			
Component	■ Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da
▼ RAID 0			
Component	■ Active	 10.144.97.87	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.87	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.87	 Local ATA Disk (naa.55cd2e404c0da
Witness	■ Active	 10.144.97.85	 Local ATA Disk (naa.55cd2e404c0e9

In this last example of component placement, we take the same 600GB virtual disk and apply a storage policy with RAID-5 erasure coding (Failures to Tolerate = 1). The object now consists of four components - three data components and a parity component - distributed across the four hosts in the cluster. If disk or host containing any one of these components is offline, the data is still accessible. If one of these components are permanently lost, Virtual SAN can rebuild the lost data or parity component from the other three surviving components.

Type	Component State	Host	1 ▲ Cache Disk Name
▼ RAID 5			
Component	■ Active	 10.144.97.85	 Local ATA Disk (naa.55cd2e404c0e9
Component	■ Active	 10.144.97.86	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.87	 Local ATA Disk (naa.55cd2e404c0da
Component	■ Active	 10.144.97.88	 Local ATA Disk (naa.55cd2e404c0da

Virtual SAN requires a minimum number of hosts depending on the failure tolerance method and number of failures to tolerate (FTT) configurations. For example, a minimum of three hosts are needed for FTT=1 with RAID-1 mirroring. A minimum of four hosts are required for FTT=1 with RAID-5 erasure coding. More implementation details and recommendations can be found in the [Virtual SAN Design and Sizing Guide](#).

Rack Awareness

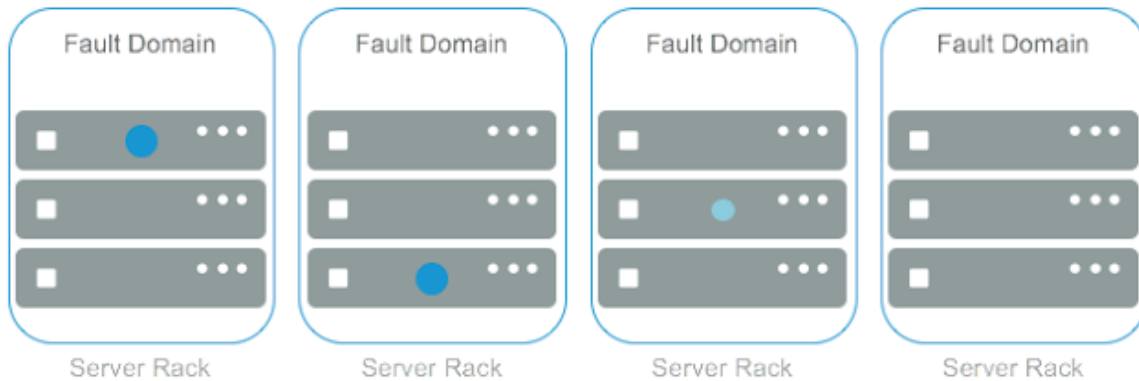

Fault Domains

"Fault domain" is a term that comes up fairly often in availability discussions. In IT, a fault domain usually refers to a group of servers, storage, and/or networking components that would be impacted collectively by an outage. A very common example of this is a server rack. If a top-of-rack (TOR) switch or the power distribution unit (PDU) for a server rack would fail, it would take all of the servers in that rack offline even though the servers themselves are functioning properly. That server rack is considered a fault domain.

Rack Awareness

While the failure of a disk or entire host can be tolerated, what if all of these servers are in the same rack and the TOR switch goes offline? Answer: All hosts are isolated from each other and none of the

objects are accessible. To mitigate this risk, the servers in a Virtual SAN cluster should be spread across server racks and fault domains must be configured in the Virtual SAN user interface. After fault domains are configured, Virtual SAN will redistribute the components across server racks to eliminate the risk of a rack failure taking multiple objects offline. This feature is commonly referred to as "Rack Awareness". The diagram below shows what this might look like with a 12-node Virtual SAN cluster spread across four server racks.

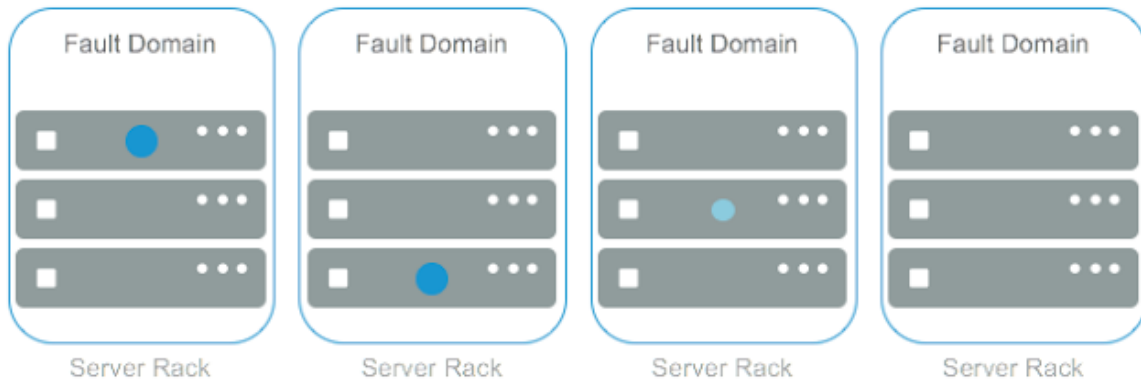

Configuring Virtual SAN fault domains is quite simple as demonstrated in this video (no audio): [Virtual SAN Fault Domains](#)

Fault Domains

In IT, a fault domain usually refers to a group of servers, storage, and/or networking components that would be impacted collectively by an outage. A very common example of this is a server rack. If a top-of-rack (TOR) switch or the power distribution unit (PDU) for a server rack would fail, it would take all of the servers in that rack offline even though the servers themselves are functioning properly. That server rack is considered a fault domain.

Rack Awareness

While the failure of a disk or entire host can be tolerated, what if all of these servers are in the same rack and the TOR switch goes offline? Answer: All hosts are isolated from each other and none of the objects are accessible. To mitigate this risk, the servers in a Virtual SAN cluster should be spread across server racks and fault domains must be configured in the Virtual SAN user interface. After fault domains are configured, Virtual SAN will redistribute the components across server racks to eliminate the risk of a rack failure taking multiple objects offline. This feature is commonly referred to as "Rack Awareness". The diagram below shows what this might look like with a 12-node Virtual SAN cluster spread across four server racks.

This feature could also be used to create a highly available Virtual SAN across

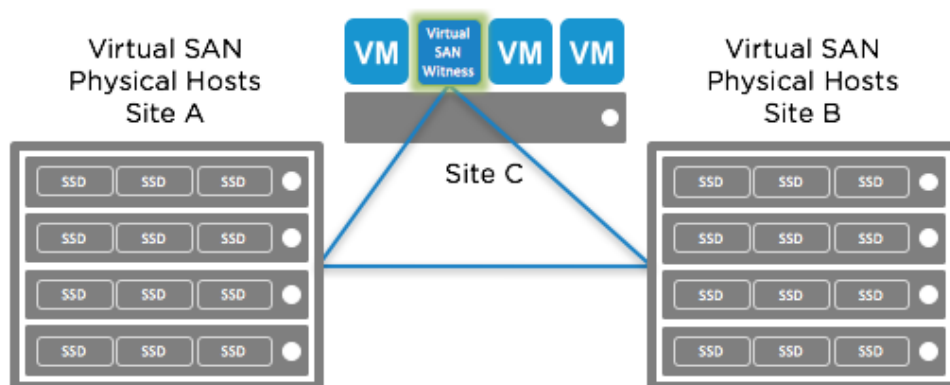

Stretched Clusters

Stretched Clusters

Virtual SAN Stretched Clusters provide organizations with the capability to deploy a Virtual SAN cluster across two locations. These locations can be opposite sides of the same data center, two buildings on the same campus, or geographically dispersed between two cities. It is important to note that this technology does have bandwidth and latency requirements as detailed in the [Virtual SAN Stretched Cluster Guide and 2-Node Guide](#).

A stretched cluster provides resiliency against larger scale outages and disasters by keeping two copies of the data - one at each location. If a failure occurs at either location, all data is available at the other location. vSphere HA restarts any virtual machines affected by the outage using the copy of the data at the surviving location. In the case of disaster avoidance such as an impending storm or rising flood waters, virtual machines can be migrated from one location to the other with no downtime using vMotion.

Since Virtual SAN is a clustering technology, a witness is required to achieve quorum in the case of a "split-brain" scenario where the two locations lose network connectivity. A Virtual SAN witness is simply a virtual machine running ESXi. The witness is deployed at a third location (separate from the two primary data locations) to avoid being affected by any issues that could occur at either of the main sites.

The witness does not store data such as virtual disk (VMDK) objects. Only witness objects are stored in the witness virtual appliance. If any one of the three sites goes offline, there is still more than 50% of each object's components online to achieve quorum and maintain availability.

7. Space Efficiency

Maximize usable capacity with space efficiency features such as deduplication, compression, and erasure coding.

Deduplication and Compression

Deduplication and Compression

Enabling deduplication and compression can reduce the amount of physical storage consumed by as much as 7x, resulting in a lower total cost of ownership (TCO). Environments with highly-redundant data such as full-clone virtual desktops and homogenous server operating systems will naturally benefit the most from deduplication. Likewise, compression will offer more favorable results with data that compresses well such as text, bitmap, and program files. Data that is already compressed such as certain graphics formats and video files, as well as files that are encrypted, will yield little or no reduction in storage consumption from compression. In other words, deduplication and compression results will vary based on the types of data stored in an all-flash Virtual SAN environment.

Deduplication and compression is a single cluster-wide setting that is disabled by default and can be enabled using a simple drop-down menu. Note that a rolling format of all disks in the Virtual SAN cluster is required, which can take a considerable amount of time. However, this process does not incur virtual machine downtime and can be done online, usually during an upgrade. Deduplication and compression are enabled as a unit. It is not possible to enable deduplication or compression individually.

Deduplication and compression are implemented after write acknowledgement to minimize impact to performance. Deduplication occurs when data is de-staged from the cache tier to the capacity tier of an all-flash Virtual SAN datastore. The deduplication algorithm utilizes a 4K-fixed block size and is performed within each disk group. In other words, redundant copies of a block within the same disk group are reduced to one copy, but redundant blocks across multiple disk groups are not deduplicated.

The compression algorithm is applied after deduplication has occurred just before the data is written to the capacity tier. Considering the additional compute resource and allocation map overhead of compression, Virtual SAN will only store compressed data if a unique 4K block can be reduced to 2K or less. Otherwise, the block is written uncompressed to avoid the use of additional resources when compressing and decompressing these blocks which would provide little benefit.

The processes of deduplication and compression on any storage platform incur overhead and potentially impact performance in terms of latency and maximum IOPS. Virtual SAN is no exception.

However, considering deduplication and compression are only supported in all-flash Virtual SAN configurations, these effects are predictable in the majority of use cases. The extreme performance and low latency of flash devices easily outweigh the additional resource requirements of deduplication and compression. The space efficiency generated by deduplication and compression lowers the cost-per-usable-GB of all-flash configurations.

RAID-5/6 Erasure Coding

RAID-5/6 Erasure Coding

RAID-5/6 erasure coding is a space efficiency feature optimized for all-flash configurations. Erasure coding provides the same levels of redundancy as mirroring, but with a reduced capacity requirement. In general, erasure coding is a method of taking data, breaking it into multiple pieces and spreading it across multiple devices, while adding parity data so it may be recreated in the event one of the pieces is corrupted or lost.

Erasure coding, FTT=1

Unlike deduplication and compression, which offer variable levels of space efficiency, erasure coding guarantees capacity reduction over a mirroring data protection method at the same failure tolerance level. As an example, let's consider a 100GB virtual disk. Surviving one disk or host failure requires 2 copies of data at 2x the capacity, i.e., 200GB. If RAID-5 erasure coding is used to protect the object, the 100GB virtual disk will consume 133GB of raw capacity - a 33% reduction in consumed capacity versus RAID-1 mirroring.

While erasure coding provides significant capacity savings over mirroring, understand that erasure coding requires additional processing overhead. This is common among any storage platform today. Erasure coding is only supported in all-flash Virtual SAN configurations. Therefore, performance impact is negligible in most use cases due to the inherent performance of flash devices. Also note that RAID-5 erasure coding (FTT=1) requires a minimum of four hosts and RAID-6 erasure coding requires a minimum of six hosts.

8. Quality of Service

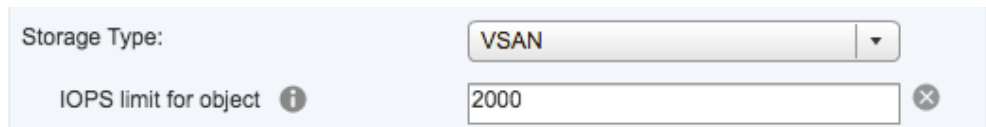

Quality of Service

IOPS Limits

Limiting IOPS

Virtual SAN has the ability to limit the number of IOPS a virtual machine or virtual disk generates. There are situations where it is advantageous to limit the IOPS of one or more virtual machines. The term noisy neighbor is often used to describe when a workload monopolizes available I/O or other resources, which negatively impact other workloads or tenants in the same environment.

An example of a possible noisy neighbor scenario is month-end reporting. Management requests delivery of these reports on the second day of each month so the reports are generated on the first day of each month. The virtual machines that run the reporting application and database are dormant most of the time. Running the reports take just a few hours, but this generates very high levels of storage I/O. The performance of other workloads in the environment are impacted while the reports are running. To remedy this issue, an administrator creates a storage policy with an IOPS limit rule and assigns the policy to the virtual machines running the reporting application and database. The IOPS limit eliminates the performance impact to the other virtual machines. The reports take longer, but they are still finished in plenty of time for delivery the next day.

The image shows a configuration interface for a storage policy. It features two main fields: 'Storage Type' with a dropdown menu currently showing 'VSAN', and 'IOPS limit for object' with an information icon and a text input field containing the value '2000'. There is also a small 'x' icon next to the IOPS limit field, likely for clearing the input.

Keep in mind storage policies can be dynamically created, modified, and assigned to virtual machines. If an IOPS limit is proving to be too restrictive, simply modify the existing policy or create a new policy with a different IOPS limit and assign it to the virtual machines. The new or updated policy will take effect just moments after the change is made.

9. Summary

Summary

Summary

Summary

Virtual SAN is optimized for modern all-flash storage with space efficiency features such as deduplication, compression, and erasure coding that lower TCO while delivering incredible performance. Hardware expenditures are further reduced for 2-node cluster configurations using directly connected crossover cables. This lowers network switch costs, reduces complexity, and improves reliability especially for use cases such as remote offices. The Virtual SAN iSCSI target service enables physical servers and application cluster workloads to utilize a Virtual SAN datastore. The performance and health services make it easy to verify Virtual SAN configurations and closely monitor key metrics including IOPs, throughput, and latency at the cluster, host, virtual machine, and virtual disk levels. Quality of service can be managed by using IOPs limits on a per-virtual machines and per-virtual disk basis. All of these services are precisely managed using VM-centric storage policies. Virtual SAN scales to 64 nodes per cluster with up to 150k IOPS per node using the latest hardware innovations such as NVMe. Deployment options include Virtual SAN Ready Nodes, Dell EMC VxRail turnkey appliances, and build-your-own. All of these utilize components certified by VMware and the leading hardware OEMs to simplify hyper-converged infrastructure deployment. This provides organizations a vast number of options to run any app, any scale on an enterprise-class platform powered by Virtual SAN.
